GENOME DEFINITIONS*

Used for Codon Bias Analysis Assignment.

* Short definition of terms. Please note that all of these have a lot more nuanced detail about them.

Genome: The entire genetic sequence of an organism or virus.

Nucleotide: Building blocks of DNA and RNA. Sequences are written with 4 letters: A, T, C, and G.

Codon: A group of 3 nucleotides that codes for a specific amino acid or signals a stop.

Amino Acid: The building block of a protein, usually represented as a single letter. Most amino acids can be created by several different codons.

Stop Codon: One of 3 codons (TAA, TAG, TGA) that does not code for an amino acid.

Codon Bias: Since most amino acids can be created by multiple codons, this is the analysis of which codons an organism uses most often for each amino acid.
